A tour of the Haskell Prelude
1 Haskell

The Haskell language was conceived during a meeting held at the 1987 Functional Programming and Computer Architecture conference (FPCA 87). At the time of the conference it was believed that the advancement of functional programming was being stifled by the wide variety of languages available. There were more than a dozen lazy, purely functional languages in existence and none had widespread support (except perhaps Miranda\(^*\)). A committee was formed to design the language. The name Haskell was chosen in honour of the mathematician Haskell Curry, whose research forms part of the theoretical basis upon which many functional languages are implemented. Haskell is widely used within the functional programming community, and there exists a number of implementations. In 1998 the Haskell community agreed upon a standard definition of the language and supporting libraries. One of the aims of standardisation was to encourage the creation of text books and courses devoted to the language. The resulting language definition is called Haskell 98.

Haskell is a lazy functional language with polymorphic higher-order functions, algebraic data types and list comprehensions. It has an extensive module system, and supports ad-hoc polymorphism (via classes). Haskell is purely functional, even for I/O. Most Haskell implementations come with a number of libraries supporting arrays, complex numbers, infinite precision integers, operating system interaction, concurrency and mutable data structures. There is a popular interpreter (called Hugs) and many compilers. More information about the Haskell language can be found on following the web-page: [www.haskell.org](http://www.haskell.org).

Hugs\(^1\) is a freely available interpreter for Haskell, which runs under Unix, Macintosh, and Microsoft Windows. One of the main features of Hugs is that it provides an interactive programming environment which allows the programmer to edit scripts, and evaluate arbitrary Haskell expressions. Hugs is based significantly on Mark Jones' Gofer interpreter. More information about the Hugs interpreter can be found on the following web-page: [www.haskell.org/hugs](http://www.haskell.org/hugs).

The following chapter serves as a reference guide to the Haskell language (specifically Haskell 98). In particular it concentrates on the content of the Haskell Prelude, which is a standard library accessible by all Haskell programs. The chapter does not give complete coverage to the whole Prelude, but instead concentrates on those aspects most useful to Haskell beginners (however it should serve as a valuable resource to experienced Haskell programmers as well). The first part of the chapter deals with Prelude functions, the second part of the chapter deals with Prelude operators, and the third part of the chapter deals with Prelude classes.

\(^*\)Miranda is a trademark of Research Software, Ltd.

\(^1\)Haskell Users' Gofer System
1.1 Functions from the Haskell Prelude

**abs**

```
type: abs :: Num a => a -> a
description: returns the absolute value of a number.
definition: abs x
    | x >= 0 = x
    | otherwise = -x
usage: Prelude> abs (-3)
        3
```

**all**

```
type: all :: (a -> Bool) -> [a] -> Bool
description: applied to a predicate and a list, returns True if all elements of the list satisfy the predicate, and False otherwise. Similar to the function any.
definition: all p xs = and (map p xs)
usage: Prelude> all (<11) [1..10]
        True
        Prelude> all isDigit "123abc"
        False
```

**and**

```
type: and :: [Bool] -> Bool
description: takes the logical conjunction of a list of boolean values (see also 'or').
definition: and xs = foldr (&&) True xs
usage: Prelude> and [True, True, False, True]
        False
        Prelude> and [True, True, True, True]
        True
        Prelude> and []
        False
```

**any**

```
type: any :: (a -> Bool) -> [a] -> Bool
description: applied to a predicate and a list, returns True if any of the elements of the list satisfy the predicate, and False otherwise. Similar to the function all.
definition: any p xs = or (map p xs)
usage: Prelude> any (<11) [1..10]
        True
        Prelude> any isDigit "123abc"
        True
        Prelude> any isDigit "alphabets"
        False
```
atan

type: atan :: Floating a => a -> a

description: the trigonometric function inverse tan.

definition: defined internally.

usage: Prelude> atan pi
1.26263

break

type: break :: (a -> Bool) -> [a] -> ([a],[a])

description: given a predicate and a list, breaks the list into two lists (returned as a tuple) at the point where the predicate is first satisfied. If the predicate is never satisfied then the first element of the resulting tuple is the entire list and the second element is the empty list ([]).

definition: break p xs
  = span p' xs
  where
  p' x = not (p x)

usage: Prelude> break isSpace "hello there fred"
("hello", " there fred")
Prelude> break isDigit "no digits here"
("no digits here","")

ceiling

type: ceiling :: (RealFrac a, Integral b) => a -> b

description: returns the smallest integer not less than its argument.

usage: Prelude> ceiling 3.8
4
Prelude> ceiling (-3.8)
-3

note: the function floor has a related use to ceiling.

chr

type: chr :: Int -> Char

description: applied to an integer in the range 0 - 255, returns the character whose ascii code is that integer. It is the converse of the function ord. An error will result if chr is applied to an integer outside the correct range.

definition: defined internally.

usage: Prelude> chr 65
'A'
Prelude> (ord (chr 65)) == 65
True

concat
type: \texttt{concat :: [[a]] -> [a]}  
description: applied to a list of lists, joins them together using the \texttt{++} operator.  
definition: \texttt{concat \textit{xs} = foldr (++) [] \textit{xs}}  
usage: Prelude> \texttt{concat [[1,2,3], [4], [], [5,6,7,8]]}  
\texttt{[1, 2, 3, 4, 5, 6, 7, 8]}  

\textbf{cos}  

\textbf{type}: \texttt{cos :: Floating a => a -> a}  
\textbf{description}: the trigonometric cosine function, arguments are interpreted to be in radians.  
\textbf{definition}: defined internally.  
\textbf{usage}: Prelude> \texttt{cos \textit{pi}}  
\texttt{-1.0}  
Prelude> \texttt{cos (\textit{pi}/2)}  
\texttt{-4.37114e-08}  

\textbf{digitToInt}  

\textbf{type}: \texttt{digitToInt :: Char -> Int}  
\textbf{description}: converts a digit character into the corresponding integer value of the digit.  
\textbf{definition}: \texttt{digitToInt :: Char -> Int}  
\begin{verbatim}  
digitToInt \textit{c}  
  | isDigit \textit{c} = fromEnum \textit{c} - fromEnum '0'  
  | \textit{c} \geq 'a' \&\& \textit{c} \leq 'f' = fromEnum \textit{c} - fromEnum 'a' + 10  
  | \textit{c} \geq 'A' \&\& \textit{c} \leq 'F' = fromEnum \textit{c} - fromEnum 'A' + 10  
  | otherwise = error "Char.digitToInt: not a digit"  
\end{verbatim}  
\textbf{usage}: Prelude> \texttt{digitToInt '3'}  
\texttt{3}  

\textbf{div}  

\textbf{type}: \texttt{div :: Integral a => a -> a -> a}  
\textbf{description}: computes the integer division of its integral arguments.  
\textbf{definition}: defined internally.  
\textbf{usage}: Prelude> \texttt{16 \textasciitilde div\textasciitilde 9}  
\texttt{1}  

\textbf{doReadFile}  

\textbf{type}: \texttt{doReadFile :: String -> String}  
\textbf{description}: given a filename as a string, returns the contents of the file as a string. Returns an error if the file cannot be opened or found.  
\textbf{definition}: defined internally.
usage: Prelude> doReadFile "foo.txt"
"This is a small text file,\ncalled foo.txt.\n"

note: This is not a standard Haskell function. You must import the
MultLib.hs module to use this function.

drop

type:     drop :: Int -> [a] -> [a]
description: applied to a number and a list, returns the list with the specified number of elements removed from the front of the list. If the list has less than the required number of elements then it returns [].
definition: drop 0 xs = xs
drop _ [] = []
drop n (-:xs) | n>0 = drop (n-1) xs
drop _ _ = error "PreludeList.drop: negative argument"

usage: Prelude> drop 3 [1..10]
[4, 5, 6, 7, 8, 9, 10]
Prelude> drop 4 "abc"
"

dropWhile

type:     dropWhile :: (a -> Bool) -> [a] -> [a]
description: applied to a predicate and a list, removes elements from the front of the list while the predicate is satisfied.
definition: dropWhile p [] = []
dropWhile p (x:xs)
  | p x = dropWhile p xs
  | otherwise = (x:xs)

usage: Prelude> dropWhile (<5) [1..10]
[5, 6, 7, 8, 9, 10]

elem

type:     elem :: Eq a => a -> [a] -> Bool
description: applied to a value and a list returns True if the value is in the list and False otherwise. The elements of the list must be of the same type as the value.
definition: elem x xs = any (== x) xs

usage: Prelude> elem 5 [1..10] True
Prelude> elem "rat" ["fat", "cat", "sat", "flat"] False

error

type:     error :: String -> a
description: applied to a string creates an error value with an associated message. Error values are equivalent to the undefined value (undefined), any attempt to access the value causes the program to terminate and print the string as a diagnostic.

definition: defined internally.

usage: error "this is an error message"

exp

type: exp :: Floating a => a -> a

description: the exponential function (exp n is equivalent to $e^n$).

definition: defined internally.

usage: Prelude> exp 1
2.71828

filter

type: filter :: (a -> Bool) -> [a] -> [a]

description: applied to a predicate and a list, returns a list containing all the elements from the argument list that satisfy the predicate.

definition: filter p xs = [k | k <- xs, p k]

usage: Prelude> filter isDigit "fat123cat456" "123456"

flip

type: flip :: (a -> b -> c) -> b -> a -> c

description: applied to a binary function, returns the same function with the order of the arguments reversed.

definition: flip f x y = f y x

usage: Prelude> flip elem [1..10] 5
True

floor

type: floor :: (RealFrac a, Integral b) => a -> b

description: returns the largest integer not greater than its argument.

usage: Prelude> floor 3.8
3
Prelude> floor (-3.8)
-4

note: the function ceiling has a related use to floor.

foldl

type: foldl :: (a -> b -> a) -> a -> [b] -> a

description: folds up a list, using a given binary operator and a given start value, in a left associative manner.
foldl op r [a, b, c] → ((r 'op' a) 'op' b) 'op' c

definition:  foldl f z [] = z
foldl f z (x:xs) = foldl f (f z x) xs

usage:      Prelude> foldl (+) 0 [1..10]
            55
Prelude> foldl (flip (:+)) [] [1..10]
            [10, 9, 8, 7, 6, 5, 4, 3, 2, 1]

foldl1

type:       foldl1 :: (a -> a -> a) -> [a] -> a

description: folds left over non-empty lists.

definition: foldl1 f (x:xs) = foldl f x xs

usage:      Prelude> foldl1 max [1, 10, 5, 2, -1]
            10

foldr

type:       foldr :: (a -> b -> b) -> b -> [a] -> b

description: folds up a list, using a given binary operator and a given start value, in a right associative manner.

        foldr op r [a, b, c] → a 'op' (b 'op' (c 'op' r))

definition: foldr f z [] = z
foldr f z (x:xs) = f x (foldr f z xs)

usage:      Prelude> foldr (++) [] ["con", "cat", "en", "ate"]
            "concatenate"

foldr1

type:       foldr1 :: (a -> a -> a) -> [a] -> a

description: folds right over non-empty lists.

definition: foldr1 f [x] = x
foldr1 f (x:xs) = f x (foldr1 f xs)

usage:      Prelude> foldr1 (*) [1..10]
            3628800

fromInt

type:       fromInt :: Num a => Int -> a

description: Converts from an Int to a numeric type which is in the class Num.

usage:      Prelude> (fromInt 3)::Float
            3.0

fromInteger
type: fromInteger :: Num a => Integer -> a

description: Converts from an Integer to a numeric type which is in the class Num.

usage: Prelude> (fromInteger 10000000000):Float
1.0e+10

fst

type: fst :: (a, b) -> a

description: returns the first element of a two element tuple.

definition: fst (x, _) = x

usage: Prelude> fst ("harry", 3)
"harry"

head

type: head :: [a] -> a

description: returns the first element of a non-empty list. If applied to an empty list an error results.

definition: head (x:_:_) = x

usage: Prelude> head [1..10]
1
Prelude> head ["this", "and", "that"]
"this"

id

type: id :: a -> a

description: the identity function, returns the value of its argument.

definition: id x = x

usage: Prelude> id 12
12
Prelude> id (id "fred")
"fred"
Prelude> (map id [1..10]) == [1..10]
True

init

type: init :: [a] -> [a]

description: returns all but the last element of its argument list. The argument list must have at least one element. If init is applied to an empty list an error occurs.

definition: init [x] = []
init (x:xs) = x : init xs

usage: Prelude> init [1..10]
[1, 2, 3, 4, 5, 6, 7, 8, 9]
**isAlpha**

type: isAlpha :: Char -> Bool

description: applied to a character argument, returns True if the character
is alphabetic, and False otherwise.

definition: isAlpha c = isUpper c || isLower c

usage: Prelude> isAlpha 'a'
True
Prelude> isAlpha '1'
False

**isDigit**

type: isDigit :: Char -> Bool

description: applied to a character argument, returns True if the character
is a numeral, and False otherwise.

definition: isDigit c = c >= '0' && c <= '9'

usage: Prelude> isDigit '1'
True
Prelude> isDigit 'a'
False

**isLower**

type: isLower :: Char -> Bool

description: applied to a character argument, returns True if the character
is a lower case alphabetic, and False otherwise.

definition: isLower c = c >= 'a' && c <= 'z'

usage: Prelude> isLower 'a'
True
Prelude> isLower 'A'
False
Prelude> isLower '1'
False

**isSpace**

type: isSpace :: Char -> Bool

description: returns True if its character argument is a whitespace character
and False otherwise.

definition: isSpace c = c == ' ' || c == '	' || c == '
' || c == '' || c == 'f' || c == 'v'

usage: Prelude> dropWhile isSpace " \hello \n" "hello \n"

**isUpper**

type: isUpper :: Char -> Bool
description: applied to a character argument, returns True if the character is an upper case alphabetic, and False otherwise.
definition: isDigit c = c >= 'A' && c <= 'Z'
usage: Prelude> isUpper 'A'
    True
Prelude> isUpper 'a'
    False
Prelude> isUpper '1'
    False

iterate

type: iterate :: (a -> a) -> a -> [a]
description: iterate f x returns the infinite list [x, f(x), f(f(x)), ...].
definition: iterate f x = x : iterate f (f x)
usage: Prelude> iterate (+1) 1
        [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, .....]

last

type: last :: [a] -> a
description: applied to a non-empty list, returns the last element of the list.
definition: last [x] = x
          last (_:xs) = last xs
usage: Prelude> last [1..10]
        10

length

type: length :: [a] -> Int
description: returns the number of elements in a finite list.
definition: length [] = 0
            length (x:xs) = 1 + length xs
usage: Prelude> length [1..10]
        10

lines

type: lines :: String -> [String]
description: applied to a list of characters containing newlines, returns a list of lists by breaking the original list into lines using the newline character as a delimiter. The newline characters are removed from the result.
definition: lines [] = []
            lines (x:xs)
                = 1 : ls
                where
                (1, xs') = break (== '
') (x:xs)
                ls
                | xs' == [] = []
                | otherwise = lines (tail xs')
usage: Prelude> lines "hello world\nit’s me,\neric\n" [
"hello world", ",it’s me", , ",eric"
]

log

type: log :: Floating a => a -> a

description: returns the natural logarithm of its argument.

definition: defined internally.

usage: Prelude> log 1
0.0
Prelude> log 3.2
1.6335

map

type: map :: (a -> b) -> [a] -> [b]

description: given a function, and a list of any type, returns a list where each element is the result of applying the function to the corresponding element in the input list.

definition: map f xs = [f x | x <- xs]

usage: Prelude> map sqrt [1..5]
[1.0, 1.41421, 1.73205, 2.0, 2.23607]

max

type: max :: Ord a => a -> a -> a

description: applied to two values of the same type which have an ordering defined upon them, returns the maximum of the two elements according to the operator >=.

definition: max x y
  | x >= y = x
  | otherwise = y

usage: Prelude> max 1 2
2

maximum

type: maximum :: Ord a => [a] -> a

description: applied to a non-empty list whose elements have an ordering defined upon them, returns the maximum element of the list.

definition: maximum xs = foldl1 max xs

usage: Prelude> maximum [-10, 0, 5, 22, 13]
22

min

type: min :: Ord a => a -> a -> a

description: applied to two values of the same type which have an ordering defined upon them, returns the minimum of the two elements according to the operator <=.
definition: \[ \min x \cdot y \]
| \[ x \leq y = x \]
| otherwise = y

usage: Prelude> \min 1 \cdot 2
1

**minimum**

type: minimum :: Ord a => [a] -> a
description: applied to a non-empty list whose elements have an ordering defined upon them, returns the minimum element of the list.
definition: minimum xs = foldl1 \min xs
usage: Prelude> \begin{align*}
\text{minimum} & \ [\ -10, \ 0, \ 5, \ 22, \ 13] \\
& -10
\end{align*}

**mod**

type: mod :: Integral a => a -> a -> a -> a
description: returns the modulus of its two arguments.
definition: defined internally.
usage: Prelude> 16 \ 'mod' \ 9
7

**not**

type: not :: Bool -> Bool
description: returns the logical negation of its boolean argument.
definition: not True = False
not False = True
usage: Prelude> \begin{align*}
\text{not} & \ (3 == 4) \\
& \text{True} \\
\text{not} & \ (10 > 2) \\
& \text{False}
\end{align*}

**or**

type: or :: [Bool] -> Bool
description: applied to a list of boolean values, returns their logical disjunction (see also 'and').
definition: or xs = foldr (||) False xs
usage: Prelude> or [False, False, True, False]
True
Prelude> or [False, False, False, False]
False
Prelude> or []
False

**ord**
type: ord :: Char -> Int
description: applied to a character, returns its ascii code as an integer.
definition: defined internally.
usage: Prelude> ord 'A'
65
Prelude> (chr (ord 'A')) == 'A'
True

pi
type: pi :: Floating a => a
description: the ratio of the circumference of a circle to its diameter.
definition: defined internally.
usage: Prelude> pi
3.14159
Prelude> cos pi
-1.0

putStr
type: putStr :: String -> IO ()
description: takes a string as an argument and returns an I/O action as a result. A side-effect of applying putStr is that it causes its argument string to be printed to the screen.
definition: defined internally.
usage: Prelude> putStr "Hello World\nI’m here!"
Hello World
I’m here!

product
type: product :: Num a => [a] -> a
description: applied to a list of numbers, returns their product.
definition: product xs = foldl (*) 1 xs
usage: Prelude> product [1..10]
3628800

repeat
type: repeat :: a -> [a]
description: given a value, returns an infinite list of elements the same as the value.
definition: repeat x
  = xs
  where xs = x:xs
usage: Prelude> repeat 12
[12, 12, 12, 12, 12, 12, 12, 12, 12, 12, 12, 12 ....]
**replicate**

type: \( \text{replicate :: Int} \to \text{a} \to [\text{a}] \)
description: given an integer (positive or zero) and a value, returns a list containing the specified number of instances of that value.
definition: \( \text{replicate n x = take n (repeat x)} \)
usage: Prelude> replicate 3 "apples"
["apples", "apples", "apples"]

**reverse**

type: \( \text{reverse :: [a]} \to [\text{a}] \)
description: applied to a finite list of any type, returns a list of the same elements in reverse order.
definition: \( \text{reverse} = \text{foldl} (\text{flip} (:)) [] \)
usage: Prelude> reverse [1..10]
[10, 9, 8, 7, 6, 5, 4, 3, 2, 1]

**round**

type: \( \text{round :: (RealFrac a, Integral b) \to a} \to b \)
description: rounds its argument to the nearest integer.
usage: Prelude> round 3.2
3
Prelude> round 3.5
4
Prelude> round (-3.2)
-3

**show**

type: \( \text{show :: Show a} \to a \to \text{String} \)
description: converts a value (which must be a member of the Show class), to its string representation.
definition: defined internally.
usage: Prelude> "six plus two equals " ++ (show (6 + 2))
"six plus two equals 8"

**sin**

type: \( \text{sin :: Floating a} \to a \to a \)
description: the trigonometric sine function, arguments are interpreted to be in radians.
definition: defined internally.
usage: Prelude> sin (pi/2)
1.0
Prelude> ((sin pi)^2) + ((cos pi)^2)
1.0
snd

  type: snd :: (a, b) -> b
  description: returns the second element of a two element tuple.
  definition: snd (_, y) = y
  usage: Prelude> snd ("harry", 3)
          3

sort

  type: sort :: Ord a => [a] -> [a]
  description: sorts its argument list in ascending order. The items in the list
              must be in the class Ord.
  usage: List> sort [1, 4, -2, 8, 11, 0]
         [-2,0,1,4,8,11]
      note: This is not defined within the Prelude. You must import the
             List.hs module to use this function.

span

  type: span :: (a -> Bool) -> [a] -> ([a],[a])
  description: given a predicate and a list, splits the list into two lists (re-
              turned as a tuple) such that elements in the first list are taken
              from the head of the list while the predicate is satisfied, and
              elements in the second list are the remaining elements from the
              list once the predicate is not satisfied.
  definition: span p [] = ([],[])
              span p xs@(x:xs')
              | p x = (x:ys, zs)
              | otherwise = ([],xs)
              where (ys,zs) = span p xs'
  usage: Prelude> span isDigit "123abc456"
          (["123"], "abc456")

splitAt

  type: splitAt :: Int -> [a] -> ([a],[a])
  description: given an integer (positive or zero) and a list, splits the list into
              two lists (returned as a tuple) at the position corresponding to
              the given integer. If the integer is greater than the length of
              the list, it returns a tuple containing the entire list as its first
              element and the empty list as its second element.
  definition: splitAt 0 xs = ([],xs)
              splitAt _ [] = ([],[])
              splitAt n (x:xs)
              | n > 0 = (x:xs',xs'')
              | otherwise = ([],[]) 
              where
              (xs',xs'') = splitAt (n-1) xs
              splitAt _ _ = error "PreludeList.splitAt: negative argument"
usage: Prelude> splitAt 3 [1..10]
       ([1, 2, 3], [4, 5, 6, 7, 8, 9, 10])
Prelude> splitAt 5 "abc"
       ("abc", "")

sqrt

  type:     sqrt :: Floating a => a -> a
  description: returns the square root of a number.
  definition: sqrt x = x ** 0.5
  usage:    Prelude> sqrt 16
             4.0

subtract

  type:     subtract :: Num a => a -> a -> a
  description: subtracts its first argument from its second argument.
  definition: subtract = flip (-)
  usage:     Prelude> subtract 7 10
             3

sum

  type:     sum :: Num a => [a] -> a
  description: computes the sum of a finite list of numbers.
  definition: sum xs = foldl (+) 0 xs
  usage:     Prelude> sum [1..10]
             55

tail

  type:     tail :: [a] -> [a]
  description: applied to a non-empty list, returns the list without its first element.
  definition: tail ((_:xs)) = xs
  usage:     Prelude> tail [1,2,3]
             [2,3]
Prelude> tail "hugs"
       "ugs"

take

  type:     take :: Int -> [a] -> [a]
  description: applied to an integer (positive or zero) and a list, returns the specified number of elements from the front of the list. If the list has less than the required number of elements, take returns the entire list.

definition:  take 0 _ = []
take _ [] = []
take n (x:xs)
    | n > 0 = x : take (n-1) xs
      | otherwise = error "PreludeList.take: negative argument"

usage:    Prelude> take 4 "goodbye"
          "good"
          Prelude> take 10 [1,2,3]
          [1,2,3]

**takeWhile**

type:    takeWhile :: (a -> Bool) -> [a] -> [a]
description: applied to a predicate and a list, returns a list containing elements from the front of the list while the predicate is satisfied.
definition:    takeWhile p [] = []
takeWhile p (x:xs)
      | p x = x : takeWhile p xs
      | otherwise = []

usage:    Prelude> takeWhile (<5) [1, 2, 3, 10, 4, 2]
          [1, 2, 3]

**tan**

type:    tan :: Floating a => a -> a
description: the trigonometric function tan, arguments are interpreted to be in radians.
definition: defined internally.
usage:    Prelude> tan (pi/4)
          1.0

**toLowerCase**

type:    toLowerCase :: Char -> Char
description: converts an uppercase alphabetic character to a lowercase alphabetic character. If this function is applied to an argument which is not uppercase the result will be the same as the argument unchanged.
definition:    toLowerCase c
      | isUpper c = toEnum (fromEnum c - fromEnum 'A' + fromEnum 'a')
      | otherwise = c
usage:    Prelude> toLowerCase 'A'
          'a'
          Prelude> toLowerCase '3'
          '3'

**toUpperCase**

type:    toUpperCase :: Char -> Char
description: converts a lowercase alphabetic character to an uppercase alphabetic character. If this function is applied to an argument which is not lowercase the result will be the same as the argument unchanged.

definition: toUpper c
   | isLower c = toEnum (fromEnum c - fromEnum 'a' + fromEnum 'A')
   | otherwise = c

usage: Prelude> toUpper 'a'
   'A'
Prelude> toUpper '3'
   '3'

truncate

type: truncate :: (RealFrac a, Integral b) => a -> b
description: drops the fractional part of a floating point number, returning only the integral part.

usage: Prelude> truncate 3.2
   3
Prelude> truncate (-3.2)
   -3

note:

unlines

type: unlines :: [String] -> String
description: converts a list of strings into a single string, placing a newline character between each of them. It is the converse of the function lines.

definition: unlines xs
   = concat (map addNewLine xs)
   where
      addNewLine l = l ++ "\n"

usage: Prelude> unlines ["hello world", "it's me","eric"]
   "hello world\n it's me,\neric\n"

until

type: until :: (a -> Bool) -> (a -> a) -> a -> a
description: given a predicate, a unary function and a value, it recursively re-applies the function to the value until the predicate is satisfied. If the predicate is never satisfied until will not terminate.

definition: until p f x
   | p x = x
   | otherwise = until p f (f x)

usage: Prelude> until (>1000) (*2) 1
   1024

unwords
**unwords**

**type:** unwords :: [String] -> String

**description:** concatenates a list of strings into a single string, placing a single space between each of them.

**definition:**

```
unwords [] = []
unwords ws = foldr1 addSpace ws
where
    addSpace w s = w ++ ' ' : s
```

**usage:**

```
Prelude> unwords ["the", "quick", "brown", "fox"]
"the quick brown fox"
```

**words**

**type:** words :: String -> [String]

**description:** breaks its argument string into a list of words such that each word is delimited by one or more whitespace characters.

**definition:**

```
words s |
    findSpace == [] = []
    | otherwise = w : words s''
    where
        (w, s'') = break isSpace findSpace
        findSpace = dropWhile isSpace s
```

**usage:**

```
Prelude> words "the quick brown\n\nfox"
["the", "quick", "brown", "fox"]
```

**zip**

**type:** zip :: [a] -> [b] -> [(a,b)]

**description:** applied to two lists, returns a list of pairs which are formed by tupling together corresponding elements of the given lists. If the two lists are of different length, the length of the resulting list is that of the shortest.

**definition:**

```
zip xs ys |
    = zipWith pair xs ys
    where
        pair x y = (x, y)
```

**usage:**

```
Prelude> zip [1..6] "abcd"
[(1,'a'),(2,'b'),(3,'c'),(4,'d')]
```

**zipWith**

**type:** zipWith :: (a -> b -> c) -> [a] -> [b] -> [c]

**description:** applied to a binary function and two lists, returns a list containing elements formed by applying the function to corresponding elements in the lists.

**definition:**

```
zipWith _ _ _ = []
```

**usage:**

```
Prelude> zipWith (+) [1..5] [6..10]
[7, 9, 11, 13, 15]
```
1.2 A description of standard Haskell operators

Operators are simply functions of one or two arguments. Operators usually get written between their arguments (called infix notation), rather than to the left of them. Many operators have symbolic names (like + for plus), however this is out of convention rather than necessity. Others have completely textual names (such as ‘div’ for integer division).

The following table lists many useful operators defined in the Prelude. Definitions of *associativity* and *binding power* are given after the table.

<table>
<thead>
<tr>
<th>symbol</th>
<th>behaviour</th>
<th>type</th>
<th>associativity</th>
<th>binding power</th>
</tr>
</thead>
<tbody>

<td>Bool -&gt; Bool -&gt; Bool</td>
</tr>
</tbody>
</table>

The higher the binding power the more tightly the operator binds to its arguments.

Function application has a binding power of 10,
and so takes preference over any other operator application.
**Associativity:** sequences of operator applications are allowed in Haskell for the convenience of the programmer. However, in some circumstances the meaning of such a sequence can be ambiguous. For example, we could interpret the expression $8 - 2 - 1$ in two ways, either as $(8 - 2) - 1$, or as $8 - (2 - 1)$ (each interpretation having a different value). Associativity tells us whether a sequence of a particular operator should be bracketed to the left or to the right. As it happens, the minus operator ($-$) is left associative, and so Haskell chooses the first of the alternative interpretations as the meaning of the above expression. The choice of associativity for an operator is quite arbitrary, however, they usually follow conventional mathematical notation. Note that some operators are non-associative, which means that they cannot be applied in sequence. For example, the equality operator ($==$) is non-associative, and therefore the following expression is not allowed in Haskell: $2 == (1 + 1) == (3 - 1)$.

**Binding Power:** Haskell expressions may also contain a mixture of operator applications which can lead to ambiguities that the rules of associativity cannot solve. For example, we could interpret the expression $3 - 4 * 2$ in two ways, either as $(3 - 4) * 2$, or as $3 - (4 * 2)$ (each interpretation having a different value). Binding power tells us which operators take precedence in an expression containing a mixture of operators. The multiplication operator ($*$), has a binding power of 7 (out of a possible 10), and the minus operator ($-$) has a binding power of 6. Therefore the multiplication operator takes precedence over the minus operator, and thus Haskell chooses the second of the alternative interpretations as the meaning of the above expression. All operators must have a binding power assigned to them which ranges from 1 to 10. Function application takes precedence over everything else in an expression, and so the expression reverse [1..10] ++ [0] is interpreted as (reverse [1..10]) ++ [0], rather than reverse ([1..10] ++ [0]).

### 1.3 Using the standard Haskell operators

**!!**

**description:** given a list and a number, returns the element of the list whose position is the same as the number.

**usage:**

Prelude> [1..10] !! 0
1

Prelude> "a string" !! 3
't'

**notes:** the valid subscripts for a list $l$ are: $0 \leq \text{subscript} \leq ((\text{length } l) - 1)$. Therefore, negative subscripts are not allowed, nor are subscripts greater than one less than the length of the list argument. Subscripts out of this range will result in a program error.

**.**

**description:** composes two functions into a single function.

**usage:**

Prelude> (sqrt . sum ) [1,2,3,4,5]
3.87298

**notes:** $(f . g . h) x$ is equivalent to $f (g (h x))$. **

**
description: raises its first argument to the power of its second argument. The arguments must be in the `Floating` numerical type class, and the result will also be in that class.

usage: 

```
Prelude> 3.2**pi
38.6345
```

description: raises its first argument to the power of its second argument. The first argument must be a member of the `Num` typeclass, and the second argument must be a member of the `Integral` typeclass. The result will be of the same type as the first argument.

usage: 

```
Prelude> 3.2^4
104.858
```

`%` 

description: takes two numbers in the `Integral` typeclass and returns the most simple ratio of the two.

usage: 

```
Prelude> 20 % 4
5 % 1
Prelude> (5 % 4)^2
25 % 16
```

`*` 

description: returns the multiple of its two arguments.

usage: 

```
Prelude> 6 * 2.0
12.0
```

`/` 

description: returns the result of dividing its first argument by its second. Both arguments must be in the type class `Fractional`.

usage: 

```
Prelude> 12.0 / 2
6.0
```

`'div'` 

description: returns the integral division of the first argument by the second argument. Both arguments must be in the type class `Integral`.

usage: 

```
Prelude> 10 'div' 3
3
Prelude> 3 'div' 10
0
```

notes: `'div'` is integer division such that the result is truncated towards negative infinity.

```
Prelude> (-12) 'div' 5
-3
Prelude> 12 'div' 5
2
```
'mod'

description: returns the integral remainder after dividing the first argument by the second. Both arguments must be in the type class Integral.

usage: Prelude> 10 'mod' 3
        1
Prelude> 3 'mod' 10
        3

+

description: returns the addition of its arguments.

usage: Prelude> 3 + 4
        7
Prelude> (4 % 5) + (1 % 5)
        1 % 1

-

description: returns the subtraction of its second argument from its first.

usage: Prelude> 4 - 3
        1
Prelude> 4 - (-3)
        7

:

description: prefixes an element onto the front of a list.

usage: Prelude> 1: [2,3]
        [1,2,3]
Prelude> True: []
        [True]
Prelude> 'h':"askell"
        "haskell"

++

description: appends its second list argument onto the end of its first list argument.

usage: Prelude> [1,2,3] ++ [4,5,6]
        [1,2,3,4,5,6]
Prelude> "foo " ++ "was" ++ " here"
        "foo was here"

/= 

description: is True if its first argument is not equal to its second argument, and False otherwise. Equality is defined by the == operator. Both of its arguments must be in the Eq type class.

usage: Prelude> 3 /= 4
        True
Prelude> [1,2,3] /= [1,2,3]
        False
description: is True if its first argument is equal to its second argument, and False otherwise. Equality is defined by the \( == \) operator. Both of its arguments must be in the Eq.

usage: Prelude> 3 == 4
False
Prelude> [1,2,3] == [1,2,3]
True

description: returns True if its first argument is strictly less than its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage: Prelude> 1 < 2
True
Prelude> 'a' < 'z'
True
Prelude> True < False
False

description: returns True if its first argument is less than or equal to its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage: Prelude> 3 <= 4
True
Prelude> 4 <= 4
True
Prelude> 5 <= 4
False

description: returns True if its first argument is strictly greater than its second argument, and False otherwise. Both arguments must be in the type class Ord.

usage: Prelude> 2 > 1
True
Prelude> 'a' > 'z'
False
Prelude> True > False
True

description: returns True if its first argument is greater than or equal to its second argument, and False otherwise. Both arguments must be in the type class Ord.
Prelude> 4 >= 3
True
Prelude> 4 >= 4
True
Prelude> 4 >= 5
False

`elem`

description: returns True if its first argument is an element of the list as its second argument, and False otherwise.

usage:
Prelude> 3 `elem` [1,2,3]
True
Prelude> 4 `elem` [1,2,3]
False

`notElem`

description: returns True if its first argument is not an element of the list as its second argument.

usage:
Prelude> 3 `notElem` [1,2,3]
False
Prelude> 4 `notElem` [1,2,3]
True

&&

description: returns the logical conjunction of its two boolean arguments.

usage:
Prelude> True && True
True
Prelude> (3 < 4) && (4 < 5) && False
False

||

description: returns the logical disjunction of its two boolean arguments.

usage:
Prelude> True || False
True
Prelude> (3 < 4) || (4 > 5) || False
True

25
1.4 Type Classes from the Haskell Prelude

**Eq**

*description:* Types which are instances of this class have equality defined upon them. This means that all elements of such types can be compared for equality.

*instances:* • All Prelude types except *I0 and functions.*

*notes:* Functions which use the equality operators (==, /=) or the functions `elem` or `notElem` will often be subject to the `Eq` type class, thus requiring the constraint `Eq a =>` in the type signature for that function.

**Ord**

*description:* Types which are instances of this class have a complete ordering defined upon them.

*instances:* • All Prelude types except *I0, functions, and I0Error.*

*notes:* Functions which use the comparison operators (>, <, >=, <=), or the functions `max`, `min`, `maximum` or `minimum` will often be subject to the `Ord` type class, thus requiring the constraint `Ord a =>` in the type signature for that function.

**Enum**

*description:* Types which are instances of this class can be enumerated. This means that all elements of such types have a mapping to a unique integer, thus the elements of the type must be sequentially ordered.

*instances:* • `Bool`
  • `Char`
  • `Int`
  • `Integer`
  • `Float`
  • `Double`

*notes:* Functions which use dot-dot notation (eg `[1..y]`) in list comprehensions will often be subject to the `Enum` type class, thus requiring the constraint `Enum a =>` in the type signature for that function.

**Show**

*description:* Types which are instances of this class have a printable representation. This means that all elements of such types can be given as arguments to the function `show`.

*instances:* • All Prelude types.

*notes:* Functions which use the function `show` will often be subject to the `Show` type class, thus requiring the constraint `Show a =>` in the type signature for that function.
Read

description: Types which are instances of this class allow a string representation of all elements of the type to be converted to the corresponding element.

instances: • All Prelude types except Int and functions.

notes: Functions which use the function read will often be subject to the Read type class, thus requiring the constraint Read a => in the type signature for that function.

Num

description: This is the parent class for all the numeric classes. Any type which is an instance of this class must have basic numeric operators (such as plus, minus and multiply) defined on them, and must be able to be converted from an Int or Integer to an element of the type.

instances: • Int
• Integer
• Float
• Double

notes: Functions which perform operations which are applicable to all numeric types, but not to other non-numeric types will often be subject to the Num type class, thus requiring the constraint Num a => in the type signature for that function.

Real

description: This class covers all the numeric types whose elements can be expressed as a ratio.

instances: • Int
• Integer
• Float
• Double

Fractional

description: This class covers all the numeric types whose elements are fractional. All such types must have division defined upon them, they must have a reciprocal, and must be convertible from rational numbers, and double precision floating point numbers.

instances: • Float
• Double

notes: Functions which use the division operator (/) will often be subject to the Fractional type class, thus requiring the constraint Fractional a => in the type signature for that function.

Integral

description: This class covers all the numeric types whose elements are integral.
instances:  
  • Int
  • Integer

notes:  
Functions which use the operators div or mod will often be subject to the Integral type class, thus requiring the constraint Integral a => in the type signature for that function.

Floating

description:  
This class covers all the numeric types whose elements are floating point numbers.

instances:  
  • Float
  • Double

notes:  
Functions which use the constant pi or the functions exp, log, sqrt, sin, cos or tan will often be subject to the Floating type class, thus requiring the constraint Floating a => in the type signature for that function.

1.5 The Haskell Prelude Class hierarchy

![Class Hierarchy Diagram]

Read

Figure 1: A sample of the class hierarchy from the Haskell Prelude

Figure 1 illustrates a sample of the type class hierarchy from the Haskell Prelude. Arrows in the diagram represent the ordering of classes in the hierarchy. For example, for a type to be in the class Ord it must also be in the class Eq. Note that the class Read is separate from the rest of the hierarchy.
